**PER CAPITA GREENHOUSE GAS (GHG) EMISSIONS ABOVE G20 AVERAGE**

Canada’s total GHG emissions (excl. land use) increased by 19% between 1990 and 2017.

**NOT ON TRACK FOR A 1.5°C WORLD**

Canada’s fair-share range is below 332 MtCO₂e by 2030 and below -156 MtCO₂e by 2050. Under Canada’s 2030 NDC target, emissions would only be limited to 526 MtCO₂e. Canada can achieve 1.5°C-compatibility via strong domestic emissions reductions, supplemented with contributions to global emissions reduction efforts. All figures exclude land use and are based on pre-COVID-19 projections.

**KEY OPPORTUNITIES FOR ENHANCING CLIMATE AMBITION**

- **Table climate legislation that enshrines science-based targets in law, including an enhanced 2030 target.** Five-year budgets can help achieve the 2030 target along with mechanisms for data collection, reporting, transparency and oversight.
- **Improved Buildings Efficiency**
  
  Energy efficiency, production and adoption of zero-emission vehicles, and growing Canada’s clean energy sectors.

**RECENT DEVELOPMENTS**

- **In July 2020, the federal government reversed an earlier decision and now requires a proposed coal mine expansion to undergo a federal impact assessment.** COVID-19 has delayed progress on many policies.
- **The Emergency Response Act has empowered Export Development Canada to channel public funds to prop-up domestic oil and gas operations – without a cap to the financing, public scrutiny or a sunset clause to end the changes.**
- **Canada’s September Throne Speech promises climate accountability legislation, a new NDC, enhanced climate targets and an industrial strategy around zero-emission vehicles in the coming months.**

**CORONAVIRUS RECOVERY**

Since March 2020, the federal government has been developing and implementing economic recovery measures to help individuals and businesses with the immediate financial and health impacts of the COVID-19 pandemic. Financial support for health and safety, direct support measures and tax liquidity support amounts to approximately 14% of GDP or CAD 324,922m. Any large employers that request support must publish annual climate-related financial disclosure reports and outline how they will contribute to meeting the country’s climate targets.

SOCIO-ECONOMIC CONTEXT

Human Development Index

The Human Development Index reflects life expectancy, level of education, and per capita income. Canada ranks very high on the Index.

Very high
High
Medium
Low

Canada ranks very high on the Index.

Data for 2019. Source: UNDP, 2019

Gross Domestic Product (GDP) per capita (PPP constant 2015 international $)

Canada’s population is expected to increase by about 22% from 2019 levels by 2050, and become steadily more urbanised from an already high level.

Source: The World Bank, 2019; United Nations, 2018

Death rate attributable to air pollution

More than 5,000 people die in Canada every year as a result of outdoor air pollution, due to stroke, heart disease, lung cancer and chronic respiratory diseases. Compared to total population, this is still one of the lower levels in the G20.

Data for 2016. Source: WHO, 2018

JUST TRANSITION

Canada has taken some steps towards ensuring a just transition for coal power workers; however, much work remains for other fossil fuel and high carbon sector workers and communities. Canada is a founding member of the Powering Past Coal Alliance and is committed to phasing out coal-fired electricity generation by 2030. In 2018, the government established a Task Force to engage with stakeholders on a just transition for workers as result of this phase-out. The government responded in its 2019 Budget by establishing a CAD 150m infrastructure fund to support affected communities, in addition to funding for coal worker transition centres. During the last federal election (October 2019), the government promised to pass a “Just Transition Act”, but has yet to introduce the necessary legislation.

1. ADAPTATION
ADDRESSING AND REDUCING VULNERABILITY TO CLIMATE CHANGE

Canada is vulnerable to climate change and adaptation actions are needed. On average, 15 fatalities and almost USD 1.7bn losses occur yearly due to extreme weather events. With global warming, society and its supporting sectors are increasingly exposed to severe climate events, such as increasing heatwave frequency.

ADAPTATION NEEDS

They are designed to allow comparison between regions and countries and, therefore, entail simplifications. They do not reflect local impacts within the country. Please see technical note for further information.

CORONAVIRUS RECOVERY
The 2020 Speech from the Throne focused on COVID-19 recovery. It commits Canada to taking action on extreme climate risks by retrofitting homes and buildings, investing in reducing floods and wildfires, adapting industries and the economy for a zero-emissions future by stimulating research and development and providing incentives to enhance competitiveness of Canada’s clean tech sectors, enhancing clean electricity, and building resilience while lowering emissions in agriculture.

Source: Governor General of Canada, 2020
Adaptation readiness
The figure shows 2000-2015 observed data from the ND-GAIN Index overlaid with projected Shared Socioeconomic Pathways (SSPs) from 2015-2060.

Canada scored well above the G20 average between 2000 and 2015 and is projected to continue doing so given its combination of social, economic and governance structures. While adaptation challenges exist, Canada is well positioned to adapt to the impacts of climate change. Socio-economic developments compatible with SSP1 and SSP2 diverge little and would increase Canada's adaptation readiness slightly more and somewhat sooner than those compatible with SSP3 due to the generally high rate of readiness.

The readiness component of the Index created by the Notre Dame Global Adaptation Initiative (ND-GAIN) encompasses social economic and governance indicators to assess a country’s readiness to deploy private and public investments in aid of adaptation. The index ranges from 0 (low readiness) to 1 (high readiness).

The overlaid SSPs are qualitative and quantitative representations of a range of possible futures. The three scenarios shown here in dotted lines are qualitatively described as a sustainable development-compatible scenario (SSP1), a middle-of-the-road (SSP2) and a ‘Regional Rivalry’ (SSP3) scenario. The shaded area delineates the G20 average in 2015 for easy reference.

2. MITIGATION
REDUCING EMISSIONS TO LIMIT GLOBAL TEMPERATURE INCREASE

Hold the increase in the global average temperature to well below 2°C above pre-industrial levels and pursue efforts to limit to 1.5°C, recognising that this would significantly reduce the risks and impacts of climate change.

EMISSIONS OVERVIEW

Canada’s GHG emissions increased by 19% (1990-2017) and the government’s climate targets for 2030 (~30% from 2005 levels) and 2050 net-zero are not in line with a 1.5°C pathway.

In 2030, global CO₂ emissions need to be 45% below 2010 levels and reach net-zero by 2050. Global energy-related CO₂ emissions must be cut by 40% below 2010 levels by 2030 and reach net-zero by 2060.

Source: Rogelj et al., 2018

GHG emissions across sectors and CAT 1.5°C ‘fair-share’ range (MtCO₂e/year)

Canada’s emissions (excl. land use) have increased by 19% between 1990 and 2017.

Canada was not on track to meet its NDC prior to the pandemic under either its current or planned policies. While emissions will drop in 2020 due to the lockdown and a slowdown in emissions is likely due to the economic impact of the pandemic, Canada is still likely to miss its 2030 target. Canada will need to scale up climate action to meet its NDC, with even more effort required to become 1.5°C ‘fair-share’ compatible, and can do so by adopting a green recovery package.

Source: Gütschow et al., 2019; Climate Action Tracker, 2020

Energy-related CO₂ emissions by sector

The largest driver of overall GHG emissions are CO₂ emissions from fuel combustion.

In Canada, the transport, energy and industry sectors are the three largest contributors to emissions.

Source: Enerdata, 2020

CORONAVIRUS RECOVERY

The federal government’s COVID-19 Economic Recovery Plan has provided CAD 2.5bn in support to the oil and gas sector to clean up orphan and inactive wells and to reduce fugitive methane emissions. Depending on how this support is structured, it could undermine the “polluter pays” principle. CAD 330m has also been provided to the country’s airports.

Source: Department of Finance Canada, 2020
**ENERGY OVERVIEW**

Fossil fuels still make up around 76% of Canada’s energy mix (including power, heat, transport fuels, etc.). Over the past three decades, the share of renewable energy has stayed at 15-16%. The carbon intensity has declined slowly in recent years.

**MITIGATION**

The share of fossil fuels in the global primary energy mix needs to fall to 67% by 2030 and to 33% by 2050 (and to substantially lower levels without Carbon Capture and Storage. Source: Rogelj et al., 2018

---

### Energy Mix

This graph shows Canada’s energy supply fuel mix and includes energy used for electricity generation, heating, cooking, as well as transport fuels. Fossil fuels (oil, coal and gas) make up 76% of Canada’s energy mix, which is slightly lower than the G20 average. The share of natural gas has increased in recent years due, in part, to the country phasing out coal in its electricity generation.

### Solar, Wind, Geothermal, and Biomass Development

Solar, wind, geothermal and biomass account for 4.5% of Canada’s energy supply – the G20 average is 6%. The share in total energy supply has decreased by around 5.9% in the last five years in Canada (2014-2019). Bioenergy (for electricity and heat) makes up the largest share.

### Decarbonisation rating: RE share of TPES compared to other G20 countries

| Current year (2019): | Low | | | | |
Carbon Intensity of the Energy Sector

Tonnes of CO₂ per unit of total primary energy supply (tCO₂/TJ)

Source: Enerdata, 2020

Decarbonisation rating: carbon intensity of the energy sector compared to other G20 countries

| 5-year trend (2014-2019): | High |
| Current year (2019): | High |

Carbon intensity shows how much CO₂ is emitted per unit of energy supply.

In Canada, carbon intensity has declined slowly in recent years, reaching 46 tCO₂/TJ in 2019, and is better than the G20 average.

Source: own evaluation

Energy supply per capita (GJ/capita)

Canada: 331 GJ/capita
G20 average: 97 GJ/capita

The level of energy use per capita is closely related to economic development, climatic conditions and the price of energy.

Energy use per capita in Canada is 331 GJ/capita, well above the G20 average, and has increased by 1.6% over the past five years (2014-2019).

Decarbonisation rating: energy supply per capita compared to other G20 countries

| 5-year trend (2014-2019): | Medium |
| Current year (2019): | Very low |

Source: own evaluation

Energy intensity of the economy (TJ/PPP USD2015 millions)

Canada: 6.46 TJ/PPP USD2015 millions
G20 average: 4.46 TJ/PPP USD2015 millions

This indicator quantifies how much energy is used for each unit of GDP, which is closely related to the level of industrialisation, efficiency, climatic conditions and geography.

Canada’s energy intensity is one of the highest in the G20 and is decreasing at a slower rate compared to the G20.

Decarbonisation rating: energy intensity compared to other G20 countries

| 5-year trend (2013-2018): | Low |
| Current year (2018): | Very low |

Source: own evaluation
Canada currently produces 7% of electricity from coal. Its decision to phase out coal power by 2030 is in line with a 1.5°C limit. However, much of that coal-fired power generation will be replaced with natural gas instead of renewable energy, which is not in line with the 1.5°C limit.

Share in energy-related CO₂ emissions from electricity and heat production

Coal and decarbonisation

Worldwide, coal use for power generation needs to peak by 2020, and between 2030 and 2040, all the regions of the world need to phase out coal-fired power generation. Electricity generation has to be decarbonised before 2050, with renewable energy the most promising alternative.

STATUS OF DECARBONISATION

Electricity mix

Gross power generation (TWh)

Due to rounding, some graphs may sum to slightly above or below 100%.

Renewables make up for close to two thirds of Canada’s power mix, although wind and solar energy are only a small fraction of this electricity generation. The lion’s share is from hydropower. The share of coal has been declining slowly since the early 2000s and unabated coal-fired power generation will be phased out completely by 2030. In Alberta, coal generation has declined substantially, in part due to the province’s carbon pricing scheme. Much of Canada’s coal capacity is expected to be replaced with natural gas.

Share of renewables in power generation

(incl. large hydro)

Decarbonisation rating: share of renewables compared to other G20 countries

5-year trend (2014-2019):

Current year (2019):

Source: own evaluation

Source: Enerdata, 2020

Due to rounding, some graphs may sum to slightly above or below 100%.
POLICY ASSESSMENT

Renewable energy in the power sector

Canada has not set itself a long-term renewable target. Responsibility for renewable support schemes lies at provincial level, leading to large differences in policy development and implementation across provinces.

In June 2019, the Albertan government cancelled its Renewable Electricity Programme, which would have provided support for an additional 3.6 GW of power. The province is now not on track to meet its 30% renewable electricity by 2030 goal; however, the continuing falling cost of renewables may change that.

Source: own evaluation

Coal phase-out in the power sector

In 2016, Canada announced the phase-out of coal-fired electricity by 2030 and adopted federal regulations in 2018. However, much of the replacement capacity will come from natural gas. The federal government came under fire for deciding not to subject a coal mine expansion project to a federal impact assessment; however, it reversed its decision in July 2020. If approved, the expansion would increase annual coal production by 5 Mt per year beginning in 2022 for export to Asia.

Source: own evaluation

Emissions intensity of the power sector

For each kilowatt hour of electricity, 137gCO₂ is emitted in Canada, one of the lowest levels in the G20, reflecting the high share of renewables in the energy mix. Emissions-intensity has also dropped by 12.3% from 2014 to 2019, which is a faster decline than the G20 average decline of 10.3%.

Decarbonisation rating: emissions intensity compared to other G20 countries

TRANSPORT SECTOR

Emissions from energy used to transport people and goods

Direct emissions from the transport sector in Canada totalled 30% in 2019. Canada’s transport emissions are driven by its almost total reliance on oil (96%).

Share in energy-related CO₂ emissions from transport sector
Source: Enerdata, 2020

0.03%

Electricity-related emissions

30%

Direct emissions

The share of low-carbon fuels in the transport fuel mix must increase to about 60% by 2050.
Source: Rogelj et al., 2018

STATUS OF DECARBONISATION

Transport energy mix

Final energy consumption of transport by source (PJ/year)

Due to rounding, some graphs may sum to slightly above or below 100%.

Biofuels make up only 3.5% of the energy mix in transport; oil continues to dominate at just over 96% of the fuel mix for the transport sector.

POLICY ASSESSMENT

Phase out fossil fuel cars

The Zero-Emission Vehicle (ZEV) Infrastructure Programme aims at 100% of sales by 2040 (100% by 2035 would be 1.5°C compatible) and a few provinces have ZEVs already (QC, BC). A Clean Fuel Standard, including annual carbon intensity reduction requirements for liquid fuels, is set to be finalised in the fall of 2020.

The Advisory Council on Climate Action warned in May 2019 that measures are insufficient to achieve ZEV targets.

Source: own evaluation

Phase out fossil fuel heavy-duty vehicles

Canada has no plans for phasing out emissions from freight transport. In 2018, however, Canada launched the Green Freight Assessment Programme to support carriers in implementing emissions reduction strategies. Canada revised its emissions regulations for HDVs in 2018, tightening standards for model year 2021 and then again for 2027.

Source: own evaluation

Modal shift in (ground) transport

Canada’s Long-term Infrastructure Plan (2016) promises CAD 28.7bn (USD 22bn) until 2030 to spur investments in public transport infrastructure and services. One pillar of Canada’s Transportation 2030 strategy (2017) aims to shift from higher to lower emitting modes of transport. However, there are no concrete federal policies to promote a modal shift.

Source: own evaluation
Canada’s building emissions – counting heating, cooking but also electricity use – make up 15% of total CO₂ emissions. Per capita, building-related emissions are more than double the G20 average. Global emissions from buildings need to be halved by 2030, and be 80-85% below 2010 levels by 2050, mostly through increased efficiency, reduced energy demand, and electrification in conjunction with complete decarbonisation of the power sector.

Direct buildings emissions (from burning fuels for heating, etc) account for 14% of buildings sector emissions, while indirect emissions (from grid-electricity for air conditioning, appliances, etc) contribute 7% of Canada’s electricity-related CO₂ emissions.

Global emissions from buildings need to be halved by 2030, and be 80-85% below 2010 levels by 2050, mostly through increased efficiency, reduced energy demand, and electrification in conjunction with complete decarbonisation of the power sector.

POLICY ASSESSMENT

Near zero energy new buildings

Medium

Different government levels are working together on a nationwide “net-zero energy building code” by 2030 (by 2020 would be 1.5°C compatible) as well as a mandatory energy use labelling scheme. British Columbia aims for all new buildings to be net-zero energy ready by 2032.

Federal building codes are model codes that have no legal status until adopted by provincial jurisdictions.

Source: own evaluation

Renovation of existing buildings

Canada has no strategy for energy retrofitting, however, different levels of government are working together on a model code for energy retrofitting existing buildings by 2022. In July 2019, the federal government announced financial support for deep energy retrofits in residential buildings in Toronto and Hamilton.

Federal building codes are model codes that have no legal status until adopted by provincial jurisdictions.

Source: own evaluation
Industry-related emissions make up 17% of direct CO₂ emissions in Canada, a slight increase compared to 2018.

Industrial emissions need to be reduced by 65-90% from 2010 levels by 2050. Industrial emissions make up 17% of direct CO₂ emissions in Canada, a slight increase compared to 2018.

Industry-related emissions make up 17% of direct CO₂ emissions in Canada, a slight increase compared to 2018.

Steel production and steelmaking are significant GHG emission sources, and challenging to decarbonise.

POLICY ASSESSMENT

Energy Efficiency

GHG emissions from the industry sector are mainly driven by the oil and gas industry. Passed in July 2019, the federal-level Greenhouse Gas Pollution Pricing Act has a federal carbon price and a federal emissions trading system - the Output-Based Pricing System (OBPS).

The OBPS should provide a price incentive for industrial emitters to reduce greenhouse gas emissions while maintaining competitiveness and protecting against “carbon leakage”.

On 31 May 2020, an amendment to the OBPS Regulations postponed the reporting and verification processes for the 2019 compliance period from 1 June 2020 to 1 October 2020.

Several provinces have challenged the constitutionality of a mandatory federal carbon pricing system. The first two cases were decided in favour of the federal government and will now be appealed to the Supreme Court.

Source: own evaluation
In order to stay within the 1.5°C limit, Canada needs to make the land use and forest sector a net sink of emissions, e.g. by halting the expansion of residential areas and by creating new forests.

Global deforestation needs to be halted and changed to net CO₂ removals by around 2030.

Source: Rogelj et al., 2018

From 2001 to 2018, Canada lost 646 Mha of tree cover, equivalent to a 5.2% decrease since 2000. This does not take tree-cover gain into account.

Source: Global Forest Watch, 2019

Canada’s agricultural emissions come mainly from the use of synthetic fertilisers, digestive processes in animals, and livestock manure. A 1.5°C pathway requires dietary shifts, increased organic farming, and less fertiliser use.

Methane emissions (mainly enteric fermentation) need to decline to 10% by 2030 and to 35% by 2050 (from 2010 levels). Nitrous oxide emissions (mainly from fertilisers and manure) need to be reduced by 10% by 2030 and by 20% by 2050 (from 2010 levels).

Source: Rogelj et al., 2018

In Canada, the largest sources of GHG emissions in the agricultural sector are synthetic fertilisers, digestive processes in animals (enteric fermentation), and livestock manure. A shift to organic farming, more efficient use of fertilisers, and dietary changes could help reduce emissions.

Due to rounding, some graphs may sum to slightly above or below 100%.
MITIGATION: TARGETS AND AMBITION

The combined mitigation effect of nationally determined contributions (NDC) submitted by September 2020 is not sufficient and will lead to a warming of 2.7°C by the end of the century. This highlights the urgent need for all countries to submit more ambitious targets by 2020, as they agreed in 2015, and to urgently strengthen their climate action to align to the Paris Agreement’s temperature goal.

Climate Action Tracker (CAT) evaluation of NDC and actions

- Critically Insufficient
- Highly Insufficient
- Insufficient
- 2°C Compatible
- 1.5°C Compatible
- Role Model

NDCs rated “insufficient” are in the least stringent part of a country’s ‘fair-share’ range and not consistent with holding warming below 2°C, let alone with the Paris Agreement’s stronger 1.5°C limit. If all government NDCs were in this range, warming would reach over 2°C and up to 3°C.

Canada continues to implement its climate strategy, the “Pan-Canadian Framework on Clean Growth and Climate Change”; however, it remains far from meeting its NDC. Prior to the pandemic, the government was set to miss its NDC by a wide margin. Although emissions in 2020 are projected to fall due to the economic impact of the pandemic response measures, Canada is still likely to miss its 2030 NDC target, even if its additional planned policies are implemented.

Evaluation as at October 2020, based on country’s NDC. Source: Climate Action Tracker

TRANSPARENCY: FACILITATING AMBITION

Countries are expected to communicate their NDCs in a clear and transparent manner in order to ensure accountability and comparability.

The NDC Transparency Check has been developed in response to Paris Agreement decision (1/CP.21) and the Annex to decision 4/CMA.1. While the Annex is only binding from the second NDC onwards, countries are “strongly encouraged” to apply it to updated NDCs, due in 2020.

NDC Transparency Check recommendations

For more visit www.climate-transparency.org/ndc-transparency-check

To comply with the Paris Agreement by ensuring clarity, transparency and understanding, it is recommended that Canada provides the following additional information in the upcoming NDC Update (compared to the existing NDC), including:

- Provide information on circumstances under which values of the reference indicators may be updated
- Provide explicit information on whether target is single- or multi-year target.
- Provide relevant details on domestic institutional arrangements, public participation and engagement with local communities and indigenous peoples, in a gender-responsive manner.

AMBITION: LONG-TERM STRATEGIES

<table>
<thead>
<tr>
<th>Status</th>
<th>2050 target</th>
<th>Interim steps</th>
<th>Sectoral targets</th>
<th>Net-Zero target</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submitted to UNFCCC in November 2016</td>
<td>80% emission reduction goals below 2005 levels by 2050 (65% below 2005 levels excl. LULUCF)</td>
<td>30% below 2005 by 2030</td>
<td>No</td>
<td>Yes, although not yet legislated</td>
</tr>
</tbody>
</table>

The Paris Agreement invites countries to communicate mid-century, long-term, and low-GHG emissions development strategies by 2020. Long-term strategies are an essential component of the transition toward net-zero emissions and climate-resilient economies.
3. FINANCE
MAKING FINANCE FLOWS CONSISTENT WITH CLIMATE GOALS

Make finance flows consistent with a pathway towards low-GHG emissions and climate-resilient development.

Canada spent USD 2.2bn on fossil fuel subsidies in 2019, 69% of which goes to support petroleum. More than USD 3bn was raised through carbon revenues.

Investment in green energy and infrastructure needs to outweigh fossil fuels investments by 2050

Source: Rogelj et al., 2018

FISCAL POLICY LEVERS

Fiscal policy levers raise public revenues and direct public resources. Critically, they can shift investment decisions and consumer behaviour towards low-carbon, climate-resilient activities by reflecting externalities in the price.

Fossil Fuel Subsidies by fuel type

In 2019, Canada’s fossil fuel subsidies totalled USD 2.2bn (compared to USD 4.6bn in 2010, with a gradual decline amid slight fluctuations since then). 52% of the subsidies quantified were for the consumption of fossil fuels, and the remainder for their production. The highest amount of quantified subsidies was for petroleum, at USD 1.5bn, followed by natural gas, at USD 0.7bn. The royalty-reduction programmes that target specific types of oil and natural gas projects in Alberta resulted in the highest subsidies, totalling USD 0.7bn for petroleum and natural gas.

Source: OECD-IEA Fossil Fuel Support database, 2020

Due to rounding, some graphs may sum to slightly above or below 100%.

Carbon Pricing and Revenues

Since 2007, several subnational carbon taxes and emissions trading schemes have emerged in Canada. Emissions are priced between USD 15/tCO$_2$ and USD 30/tCO$_2$, with USD 5.6bn revenues generated in 2019 (estimates for some jurisdictions are missing). Subnational schemes cover between 43% and 91% of emissions. A federal carbon pricing initiative was introduced in 2019 in the form of a federal fuel charge, with pricing starting at USD 22/tCO$_2$ in 2019, increasing by USD 10 per year until it reaches USD 50/tCO$_2$ in 2022. In 2019, the federal fuel charge generated over USD 1.9bn revenues, representing the largest contribution to the yearly increase in global carbon revenues.

Source: I4CE, 2019; OECD, 2018

CORONAVIRUS RECOVERY

Any large employers that request support from the federal government’s COVID-19 Economic Recovery Plan must publish annual climate-related financial disclosure reports and outline how they will contribute to meeting the country’s climate targets. Subject to these same terms, the Large Employer Emergency Financing Facility (LEEFF) was devised in July 2020 to provide short-term liquidity through interest-bearing term loans of CAD 60m or more.

Source: Canada Development Investment Corporation, 2020
Governments steer investments through their public finance institutions, including via development banks both at home and overseas, and green investment banks. Developed G20 countries also have an obligation to provide finance to developing countries, and public sources are a key aspect of these obligations under the UNFCCC.

Public finance for fossil fuels

Between 2016 and 2018, Canada provided an average of USD 10.6bn per year in public finance for the oil and gas sector through its ECA, Export Development Canada (EDC). This represents an increase compared to the USD 8.9bn per year provided during the previous period 2013-2015. In 2016-2018, Canada was the G20 second largest supporter of fossil fuels, which is especially notable considering the relatively small size of Canada’s economy and population. No finance was identified for coal or coal-fired power production between 2016 and 2018 by the public finance institutions of Canada.

Provision of international public support

(annual average 2017 and 2018)

Climate finance contributions are sourced from Party reporting to the UNFCCC.

Bilateral, regional and other channels

Annual average contribution: 307.32 MN USD

Theme of support:
- Mitigation: 31%
- Adaptation: 20%
- Cross-cutting: 49%

Multilateral climate finance contributions

Annual average contribution: 53.97 MN USD

Theme of support:
- Cross-cutting: 75%
- Adaptation: 25%

Core / General Contributions

Annual average contribution: 139.3 MN USD

Canada’s bilateral finance increased seven-fold in the 2017/18 period compared to 2015/16. It has significant amounts of cross-cutting spending across bilateral and multilateral climate finance flows. Of the G20 countries obligated to provide climate finance, Canada’s contributions remain relatively small compared to other G20 countries. Canada’s Green Climate Fund replenishment pledge in 2019 was not more ambitious than its initial pledge in 2015.
# Financial Policy and Regulation

Through policy and regulation governments can overcome challenges to mobilising green finance, including: real and perceived risks, insufficient returns on investment, capacity and information gaps.

While regulation of securities and disclosure requirements are regulated at provincial level, the Bank of Canada (BoC) has expressed support for TCFD implementation and noted that the bank is an active member of the Green Finance Study Group. In 2018, Canada’s Minister of Environment and Climate Change and Minister of Finance jointly appointed the Expert Panel on Sustainable Finance to explore and report on opportunities and challenges faced by the country to scale and align sustainable finance with the country’s climate and economic goals. In 2019, the BoC announced a multi-year research initiative to understand better the risks that climate change poses to the economy and financial system. In March 2019, the BoC joined the Central Banks’ and Supervisors’ NGFS.

ENDNOTES

For more detail on the sources and methodologies behind the calculation of the indicators displayed, please download the Technical Note at: www.climate-transparency.org/g20-climate-performance/g20report2020

1 ‘Land use’ emissions are used here to refer to land use, land use change and forestry (LULUCF). The Climate Action Tracker (CAT) derives historical LULUCF emissions from the UNFCCC Common Reporting Format (CRF) reporting tables data converted to the categories from the IPCC 1996 guidelines, in particular separating Agriculture from Land use, land use change and forestry (LULUCF), which under the new IPCC 2006 Guidelines is integrated into Agriculture, Forestry, and Other Land Use (AFOLU).

2 The 1.5°C ‘fair-share’ ranges for 2030 and 2050 are drawn from the CAT, which compiles a wide range of perspectives on what is considered fair, including considerations such as responsibility, capability, and equality. Countries with 1.5°C fair-share ranges reaching below zero, particularly between 2030 and 2050, are expected to achieve such strong reductions by domestic emissions reductions, supplemented by contributions to global emissions reduction efforts via, for example, international finance. On a global scale, negative emissions technologies are expected to play a role from the 2030s onwards, compensating for remaining positive emissions. The CAT’s evaluation of NDCs shows the resulting temperature outcomes if all other governments were to put forward emissions reduction commitments with the same relative ambition level.

3 In order to maintain comparability across all countries, this report utilises the PRIMAP year of 2017. However, note that Common Reporting Format (CRF) data is available for countries which have recently updated GHG inventories.

4 The Decarbonisation Ratings assess the current year and average of the most recent five years (where available) to take account of the different starting points of different G20 countries.

5 The selection of policies rated and the assessment of 1.5°C compatibility are informed by the Paris Agreement, the IPCC’s 2018 SR15 and the Climate Action Tracker (2016). The table below displays the criteria used to assess a country’s policy performance.

6 This indicator adds up emissions from domestic aviation and international aviation bunkers in the respective country. In this Country Profile, however, only a radiative forcing factor of 1 s is assumed.

7 This indicator includes only direct energy-related emissions and process emissions (Scope 1) but not indirect emissions from electricity.

8 This indicator includes emissions from electricity (Scope 2) as well as direct energy-related emissions and process emissions (Scope 1).
